caspo Documentation

Release 3.0.1

Santiago Videla

October 05, 2016

Contents

CHAPTER 1

Install

In what follows we describe three alternative ways to install **caspo**:

- *Using Docker*
- *Using Anaconda*
- *Using pip*

Note that using pip requires the user to install all dependencies manually. Since installing such dependecies requires basic skills on how to compile and deploy third-party python packages it is only recommended for experienced users. Therefore, we recommend less experienced users to use either Docker or Anaconda.

1.1 Using Docker

Follow the instructions to install Docker at http://docs.docker.com. Once you have installed Docker on your computer, you can use the **caspo** docker image as follows. First you need to pull the image with:

```
$ docker pull bioasp/caspo
```

That's it. Now, you should be able to run **caspo** with docker. Usually, **caspo** will need to read and writes files to do their work. A possible way to this using docker is as follows. For safety, we recommend to use an empty directory:

```
$ mkdir caspo-wd && cd caspo-wd
```

Next, let's take a look to the command needed to run docker, mount the current directory (*caspo-wd*) into the docker container, and use it as the working directory for running **caspo**:

```
$ docker run --rm -v $PWD:/caspo-wd -w /caspo-wd bioasp/caspo
```

If you don't want to write the full docker command every time you run **caspo**, you may want to create a shell script or alias as a shortcut. For example, you may want to create a file in your working directory named *caspo* and with the following content:

```
#!/bin/sh
docker run --rm -v $PWD:/caspo-wd -w /caspo-wd bioasp/caspo $@
```

Next, make the file executable:

```
$ chmod a+x caspo
```

Now you can run **caspo** with just:

```
$ ./caspo
```

Next, go to *Testing your installation*.

1.2 Using Anaconda

NOTE: In order for this method to work, the standard C/C++ libraries must be installed in your system. In Linux you need to have gcc >= 4.9 while in OS X 10.9+ you need to install Xcode and the command line tools.

Follow the instructions to install Anaconda at https://www.continuum.io/downloads. Next, download the file `environment.yml` and use it to create a conda environment where **caspo** will be installed:

```
$ conda env create --file environment.yml
Using Anaconda Cloud api site https://api.anaconda.org
Fetching package metadata ...............
Solving package specifications: ..........
...
Linking packages ...
[      COMPLETE      ]|##################################################| 100%
#
# To activate this environment, use:
# $ source activate caspo-env
#
# To deactivate this environment, use:
# $ source deactivate
#
```

That's it. Now, you should be able to run **caspo** within the created environment. Note that you need to *activate* the environment every time you open a new terminal.

Next, go to *Testing your installation*.

1.3 Using pip

NOTE: Depending on your platform and whether you decide to use the system's python or a virtual environment, this method may require you to install additional compilers and libraries beforehand.

Essentially, you will need to have python 2.7.x and some of the standard scientific python packages installed. Download the file `requirements.txt` and install **caspo** by running:

```
$ pip install -r requirements.txt
```

Alternatively, you could download **caspo** sources and after unpacking run:

```
$ python setup.py install
```

Note that installing **caspo** in this way **does not** force the installation of any of the runtime dependencies. In other words, you take full responsibility of installing all required packages to run **caspo** successfully.

Also, the python module of the answer set programming solver clingo must be available in the PYTHONPATH. After unpacking clingo sources, you will find detailed instructions about how to compile and build the python module in the INSTALL file.

Next, go to *Testing your installation*.

1.4 Testing your installation

Once **caspo** is installed you can test the installation as follows. To start with, you can ask for help:

```
$ caspo --help
usage: caspo [-h] [--quiet] [--out O] [--version]
             {learn,classify,predict,design,control,visualize,test} ...

Reasoning on the response of logical signaling networks with ASP

optional arguments:
  -h, --help            show this help message and exit
  --quiet               do not print anything to standard output
  --out O               output directory path (Default to './out')
  --version             show program's version number and exit

caspo subcommands:
  for specific help on each subcommand use: caspo {cmd} --help

  {learn,classify,predict,design,control,visualize,test}
```

A more interesting test is to run **caspo test** to make sure all subcommands are working:

```
$ caspo test --help
usage: caspo test [-h] [--threads T] [--conf C]
                  [--testcase {Toy,LiverToy,LiverDREAM,ExtLiver}]

optional arguments:
  -h, --help            show this help message and exit
  --threads T           run clingo with given number of threads
  --conf C              threads configurations (Default to many)
  --testcase {Toy,LiverToy,LiverDREAM,ExtLiver}
                        testcase name
```

This subcommand will run all subcommands in **caspo** using different testcases (see `--testcase` argument):

```
$ caspo test

Testing caspo subcommands using test case Toy.

Copying files for running tests:
  Prior knowledge network: pkn.sif
  Phospho-proteomics dataset: dataset.csv
  Experimental setup: setup.json
  Intervention scenarios: scenarios.csv

$ caspo --out out learn out/pkn.sif out/dataset.csv 10 --fit 0.1 --size 5

Optimum logical network learned in 0.0183s
Optimum logical networks has MSE 0.1100 and size 7
5 (nearly) optimal logical networks learned in 0.0082s
Weighted MSE: 0.1100

$ caspo --out out classify out/networks.csv out/setup.json out/dataset.csv 10

Classifying 5 logical networks...
3 input-output logical behaviors found in 0.2029s
Weighted MSE: 0.1100
```

```
$ caspo --out out design out/behaviors.csv out/setup.json

1 optimal experimental designs in 0.0043s

$ caspo --out out predict out/behaviors.csv out/setup.json

Computing all predictions and their variance for 3 logical networks...

$ caspo --out out control out/networks.csv out/scenarios.csv

3 optimal intervention strategies found in 0.0047s

$ caspo --out out visualize --pkn out/pkn.sif --setup out/setup.json
        --networks out/networks.csv --midas out/dataset.csv 10
        --stats-networks=out/stats-networks.csv --behaviors out/behaviors.csv
        --designs=out/designs.csv --predictions=out/predictions.csv
        --strategies=out/strategies.csv --stats-strategies=out/stats-strategies.csv
```

If everything works as expected, you should find a directory named *out* in the current directory having all the output files generated by **caspo**.

CHAPTER 2

Usage

2.1 Input/Output files

Input and output files in **caspo** are mostly comma separated values (csv) files. Next, we describe all files either consumed or produced when running **caspo** subcommands.

2.1.1 Prior knowledge network

A prior knowledge network (PKN) is given using the simple interaction format (SIF). Lines in the SIF file must specify a source node, an edge sign (1 or -1), and one target node. Note that SIF format specification also consider several target nodes per line but this is not supported in **caspo** at the moment. In the example shown below we would say that *a* and *b* have a positive influence over *d* while *c* has a negative influence over *d*.

a	1	d
b	1	d
c	-1	d
b	1	e
c	1	e

2.1.2 Experimental setup

An experimental setup is given using the JSON format. The JSON file must specify three list of node names, namely, *stimuli*, *inhibitors*, and *readouts*. In the following example, *a*, *b*, and *c* are stimuli, *d* is an inhibitor while *f* and *g* are readouts.

```
{
  "stimuli": ["a", "b", "c"],
  "inhibitors": ["d"],
  "readouts": ["f", "g"]
}
```

2.1.3 Experimental dataset

A phospho-proteomics dataset is given using the MIDAS format. Notably, MIDAS format considers time-series data but as we will see later, **caspo** always requires the user to define the time-point of interest when reading a MIDAS file (see *Learn*). Different time-points of *data acquisition* are specified in columns with prefix DA:.

In the example shown below, looking at the third row we would say that, when *a* and *c* are present, i.e. stimulated, and *d* is not inhibited, i.e., the inhibitor of *d* is not present, readouts for *f* and *g* at time-point 10 are 0.9 and 0, respectively. Meanwhile, looking at the four row we would say that when *a* and *c* are present and *d* is inhibited (the inhibitor of *d* it is present), readouts for *f* and *g* at time-point 10 are 0.1 and 0.9, respectively.

TR:Toy:CellLine	TR:a	TR:b	TR:c	TR:di	DA:f	DA:g	DV:f	DV:g
1	1	0	1	0	0	0	0	0
1	1	0	1	1	0	0	0	0
1	1	0	1	0	10	10	0.9	0
1	1	0	1	1	10	10	0.1	0.9

2.1.4 Logical networks

Logical networks are given using a csv file as follows. We assume that every logical mapping in a given network is in disjunctive normal form (DNF). Thus, columns header specify all possible conjunctions targeting any given node, e.g. *d<-a+!c* (*d equals a AND NOT c*). Then, each row describes a logical network by specifying which conjunctions are present (1) in the network or not (0). Whenever, two conjunctions targeting the same node are present in a given network they are connected using OR. For example, if we look at the first row in the example below, since *d<-a* and *d<-b+!c* are both present, the complete logical mapping for *d* would be: *d equals a OR (b AND NOT c)*.

Additional columns could be included to give more details related to each network, e.g., MSE, size, or the number of networks having the same input-output behavior. See the output csv files in subcommands *Learn* (*networks.csv*) or *Classify* (*behaviors.csv*). However, when parsing a csv file of logical networks, **caspo** ignores columns that cannot be parsed as logical mappings except for a column named *networks* which is interpreted as the number of networks exhibiting the same input-output behavior (including the representative network being parsed). In particular, such a column will be relevant when computing weighted average predictions (see *Predict*).

e<-c	e<-b	d<-a	d<-!c	d<-b	d<-a+!c	d<-b+!c	f<-d+e
1	1	1	0	0	0	1	0
1	1	1	1	0	0	0	0
1	1	1	0	1	0	1	0
1	1	1	1	1	0	0	0
1	1	1	0	0	0	1	0

Basic statistics over a family of logical networks are described using a csv file as follows. For each logical mapping conjunction we compute its frequency of occurrence over all logical networks in the family. Also, mutually exclusive/inclusive pairs of mapping conjunctions are identified.

mapping	frequency	exclusive	inclusive
e<-c	1.0000		
e<-b	1.0000		
d<-a	1.0000		
d<-b+!c	0.6000	d<-!c	
d<-!c	0.4000	d<-b+!c	
d<-b	0.4000		

2.1.5 Experimental designs

An experimental design is essentially a set of experimental perturbations, i.e., various combinations of stimuli and inhibitors. But also, we describe an experimental design by how its perturbations discriminate the family of input-output behaviors (see *Design* for an example visualization). Experimental designs are given using a csv file as shown below. A column named *id* is used to identify rows corresponding to the same experimental design. Next, columns with prefix TR: correspond to experimental perturbations in the same way as in MIDAS format. Finally, for each combination of stimuli and inhibitors in a given experimental design, we count pairwise differences generated over

specific readouts (columns with prefix DIF:) and pairs of behaviors being discriminated by at least one readout (column named *pairs*).

In the example below we show one experimental design made of two experimental perturbations. The first perturbation requires *b* and *c* to be stimulated, it generates 2 pairwise differences over *f*, and it discriminates 2 pairs of behaviors. The second perturbation requires *b* to be stimulated and *d* to be inhibited, it generates 1 pairwise difference over *f*, 1 pairwise difference over *g*, and it discriminates 1 pair of behaviors.

id	TR:a	TR:b	TR:c	TR:di	DIF:f	DIF:g	pairs
0	0	1	1	0	2	0	2
0	0	1	0	1	1	1	1

2.1.6 Logical predictions

Based on the input-output classification (see *Classify*), we can compute the response of the system for every possible perturbation by combining the ensemble of predictions from all input-output behaviors. Thus, predictions of a logical networks family are given using a csv file as the (incomplete) example below. For each possible combination of stimuli and inhibitors (columns with prefix TR:), the prediction for any readout node will be the weighted average (columns with prefix AVG:) over the predictions from all input-output behaviors and where each weight corresponds to the number of networks exhibiting the corresponding behavior. Also, the mean variance over all predictions is computed (columns with prefix VAR:). See *Predict* for an example visualization of readout mean variances.

TR:a	TR:c	TR:b	TR:di	AVG:g	AVG:f	VAR:g	VAR:f
1	0	0	0	0.0	0.0	0.0	0.0
0	1	0	0	0.0	0.0	0.0	0.0
0	0	1	0	1.0	0.8	0.0	0.16
0	1	1	0	0.0	0.4	0.0	0.24

2.1.7 Intervention scenarios

An intervention scenario is simply a pair of constraints and goals over nodes in a logical network. Thus, intervention scenarios are given using a csv file as shown below. Each column specifies either a *scenario constraint* (SC:) or a *scenario goal* (SG:) over any node in the network. Next, each row in the file describes a different intervention scenario. Values can be either 1 for active, -1 for inactive, or 0 for neither active nor inactive. That is, a 0 means there are no constraint nor expectation over that node in the corresponding scenario.

In the example below, we show two intervention scenarios. The first scenario requires that both, *f* and *g* to reach the inactive state under the constraint of *a* being active. The second scenario required only *f* to reach the active state under no constraints.

SC:a	SG:f	SG:g
1	-1	-1
0	1	0

2.1.8 Intervention strategies

An intervention strategy is a set of Boolean interventions over nodes in a logical network. Thus, intervention strategies are given using a csv file as shown below. Each column specifies a Boolean intervention over a given node (prefix TR: is used for consistency with MIDAS and other csv files). Next, each row in the file describes a different intervention strategy. Values can be either 1 for active, -1 for inactive, or 0 for neither active nor inactive. That is, a 0 means there is no intervention over that node in the corresponding strategy.

TR:c	TR:b	TR:e	TR:d
0	0	-1	0
-1	-1	0	0
1	0	0	-1

Basic statistics over a set of intervention strategies are described using a csv file as follows. For each Boolean intervention we compute its frequency of occurrence over all strategies in the set. Also, mutually exclusive/inclusive pairs of interventions are identified.

intervention	frequency	exclusive	inclusive
c=-1	0.3333		b=-1
c=1	0.3333		d=-1
b=-1	0.3333		c=-1
e=-1	0.3333		
d=-1	0.3333		c=1

2.2 Command Line Interface

The command line interface (CLI) of **caspo** offers various subcommands:

- *learn*: for learning a family of (nearly) optimal logical networks
- *classify*: for classifying a family of networks wrt their I/O behaviors
- *design*: for designing experiments to discriminate a family of I/O behaviors
- *predict*: for predicting based on a family of networks and I/O behaviors
- *control*: for controlling a family of logical networks in several intervention scenarios
- *visualize*: for basic visualization of the subcommands outputs
- *test*: for running all subcommands using various examples

Next, we will see how to run each subcommand and describe their outputs.

If you haven't done it yet, start by asking **caspo** for help:

```
$ caspo --help
usage: caspo [-h] [--quiet] [--out O] [--version]
             {learn,classify,predict,design,control,visualize,test} ...

Reasoning on the response of logical signaling networks with ASP

optional arguments:
  -h, --help            show this help message and exit
  --quiet               do not print anything to standard output
  --out O               output directory path (Default to './out')
  --version             show program's version number and exit

caspo subcommands:
  for specific help on each subcommand use: caspo {cmd} --help

  {learn,classify,predict,design,control,visualize,test}
```

2.2.1 Learn

This subcommand implements the learning of logical networks given a prior knowledge network and a phosphoproteomics dataset [1, 2]. In order to account for the noise in experimental data, a percentage of tolerance with respect to the maximum fitness can be used, e.g., we use 4% in the example below. Analogously, in order to relax the parsimonious principle a tolerance with respect to the minimum size (networks complexity) can be used as well. Further, other arguments allow for controlling the data discretization or the maximum number of inputs per AND gate.

Help on **caspo learn**:

```
$ caspo learn --help
usage: caspo learn [-h] [--threads T] [--conf C] [--fit F] [--size S]
                   [--factor D] [--discretization T] [--length L]
                   pkn midas time

positional arguments:
  pkn                   prior knowledge network in SIF format
  midas                 experimental dataset in MIDAS file
  time                  time-point to be used in MIDAS

optional arguments:
  -h, --help            show this help message and exit
  --threads T           run clingo with given number of threads
  --conf C              threads configurations (Default to many)
  --optimum O           logical network in CSV format. If many networks are
                        given, the first network is used (If given, avoids
                        learning the optimum and go directly to enumeration)
  --fit F               tolerance over fitness (Default to 0)
  --size S              tolerance over size (Default to 0)
  --factor D            discretization over [0,D] (Default to 100)
  --discretization T    discretization function: round, floor, ceil (Default to
                        round)
  --length L            max conjunctions length (sources per hyperedges)
                        (Default to 0; unbounded)
```

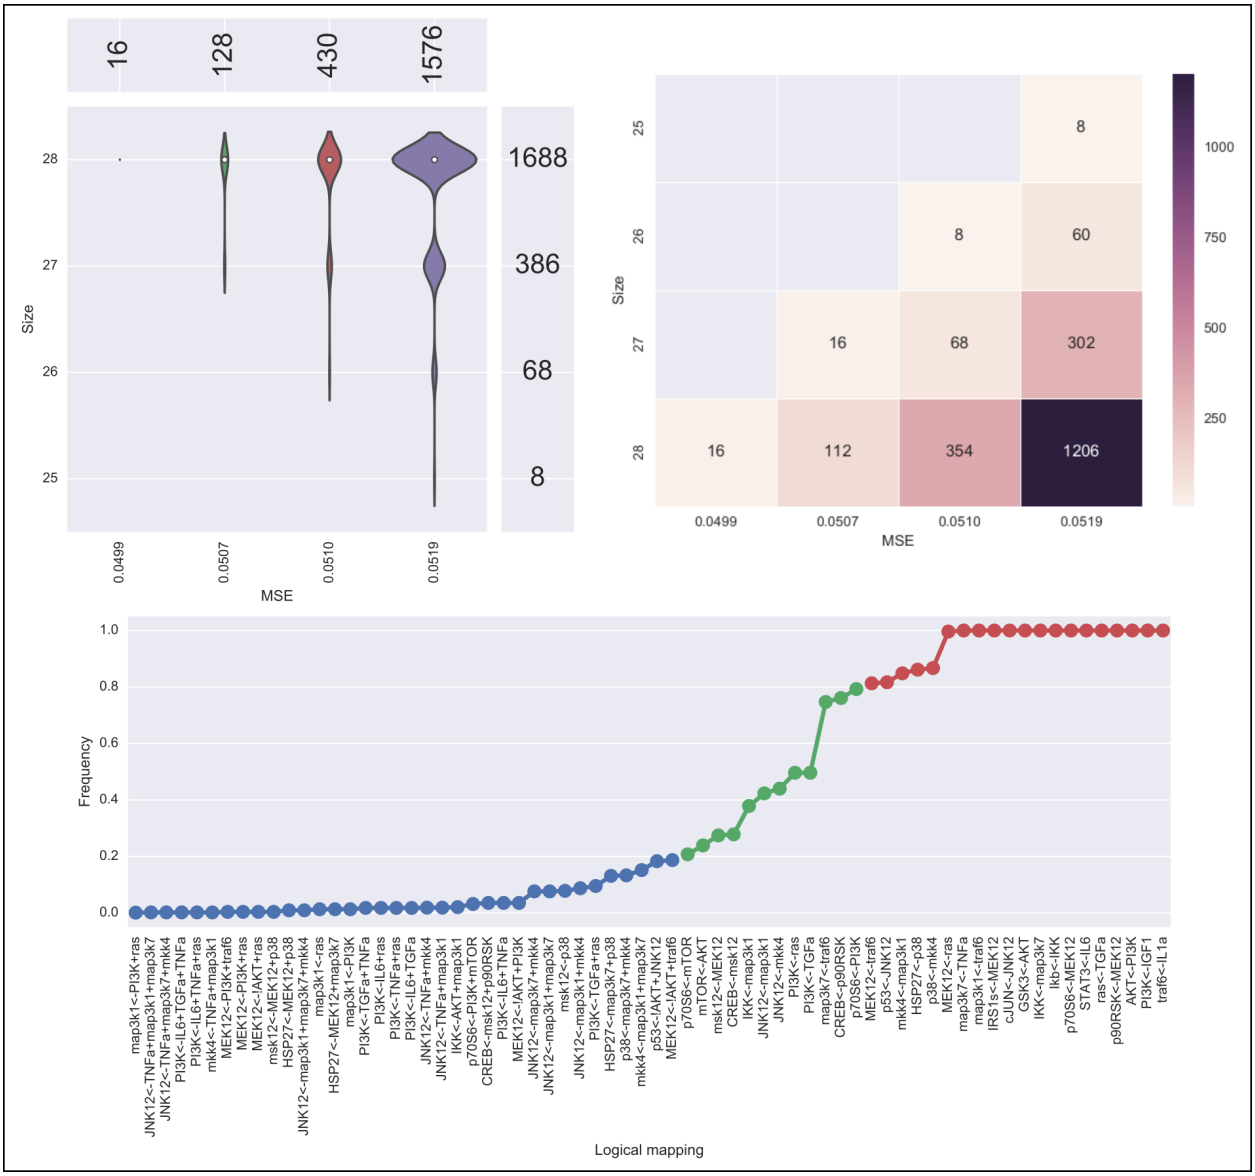
Run **caspo learn**:

```
$ caspo learn pkn.sif dataset.csv 30 --fit 0.04

Running caspo learn...
Number of hyperedges (possible logical mappings) derived from the compressed PKN: 130
Optimum logical network learned in 1.0537s
Optimum logical networks has MSE 0.0499 and size 28
2150 (nearly) optimal logical networks learned in 2.6850s
Weighted MSE: 0.0513
```

The output of **caspo learn** will be two csv files, namely, *networks.csv* and *stats-networks.csv*. The file *networks.csv* describes all logical networks found with their corresponding MSE and size. The file *stats-networks.csv* describes the frequency of each logical mapping conjunction over all networks together with pairs of mutually inclusive/exclusive mappings. The weighted MSE combining all networks is also computed and printed in the standard output.

In addition, the following default visualizations are provided describing the family of logical networks. At the top, we show two alternative ways of describing the distribution of logical networks with respect to MSE and size. At the bottom, we show the (sorted) frequencies for all logical mapping conjunctions.



2.2.2 Classify

This subcommand implements the classification of a given family of logical networks with respect to their input-output behaviors [1]. Notably, the list of networks generated by **caspo learn** can be used directly as the input for **caspo classify**.

Help on **caspo classify**:

```
$ caspo classify --help
usage: caspo classify [-h] [--threads T] [--conf C] [--midas M T]
                      networks setup

positional arguments:
  networks      logical networks in CSV format
  setup         experimental setup in JSON format

optional arguments:
```

```
  -h, --help    show this help message and exit
  --threads T   run clingo with given number of threads
  --conf C      threads configurations (Default to many)
  --midas M T   experimental dataset in MIDAS file and time-point to be used
```

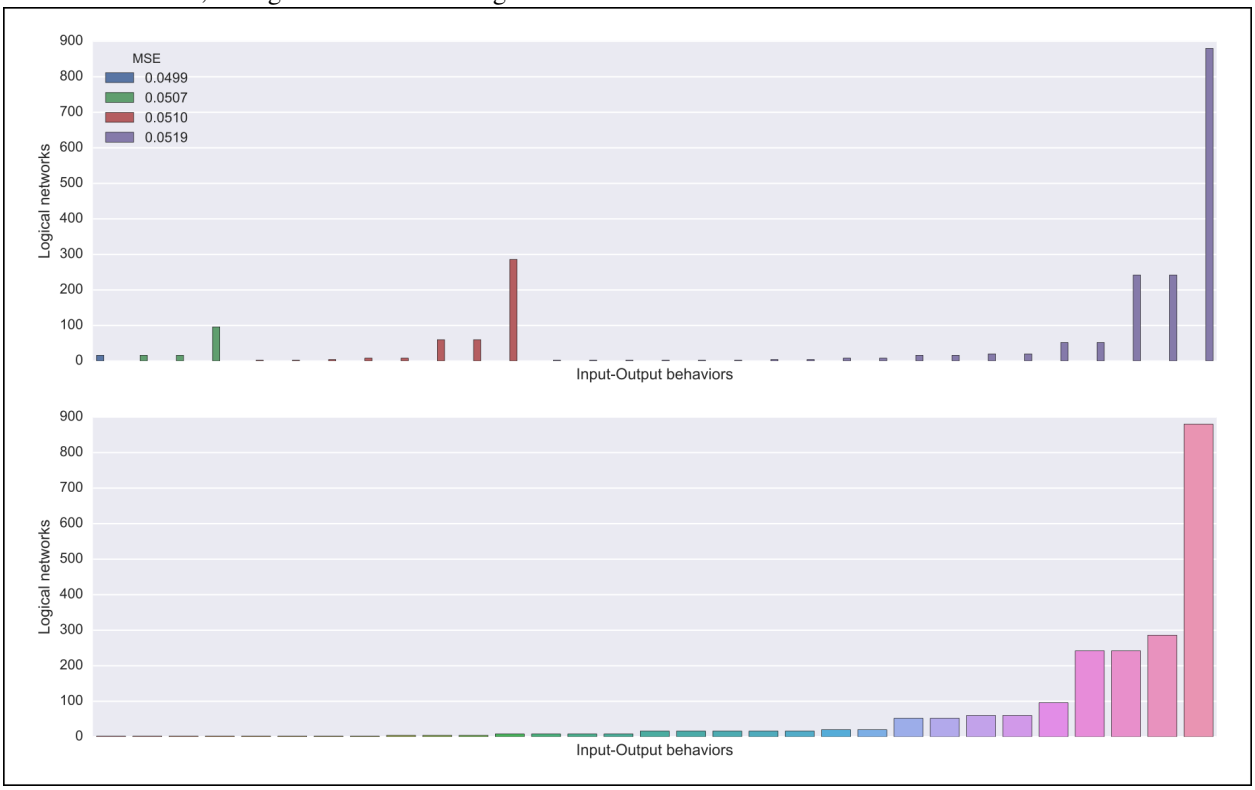
Run **caspo classify**:

```
$ caspo classify networks.csv setup.json --midas dataset.csv 30

Running caspo classify...
Classifying 2150 logical networks...
31 input-output logical behaviors found in 156.9032s
Weighted MSE: 0.0513
```

The output of **caspo classify** will be a csv file named *behaviors.csv* describing one representative logical network for each input-output behavior found among given networks. For each representative network, the number of networks having the same behavior is also given. Further, if a dataset is given, the weighted MSE is computed.

Also, one of the following visualizations is provided depending on whether the dataset was given as an argument or not. If the a dataset is given, the figure at the top is generated where I/O behaviors are grouped by MSE to the given dataset. Otherwise, the figure at the bottom is generated.



2.2.3 Design

This subcommands implements the design of novel experiments in order discriminate a given family of input-output behaviors [3]. Notably, the list of input-output behaviors generated by **caspo classify** can be used directly as the input for **caspo design**. Further, other arguments allow for controlling the maximum number of stimuli and inhibitors used per experimental condition, or the maximum number of experiments allowed.

Help on **caspo design**:

```
$ caspo design --help
usage: caspo design [-h] [--threads T] [--conf C] [--stimuli S]
                    [--inhibitors I] [--nexp E] [--list L] [--relax]
                    networks setup

positional arguments:
  networks        logical networks in CSV format
  setup           experimental setup in JSON format

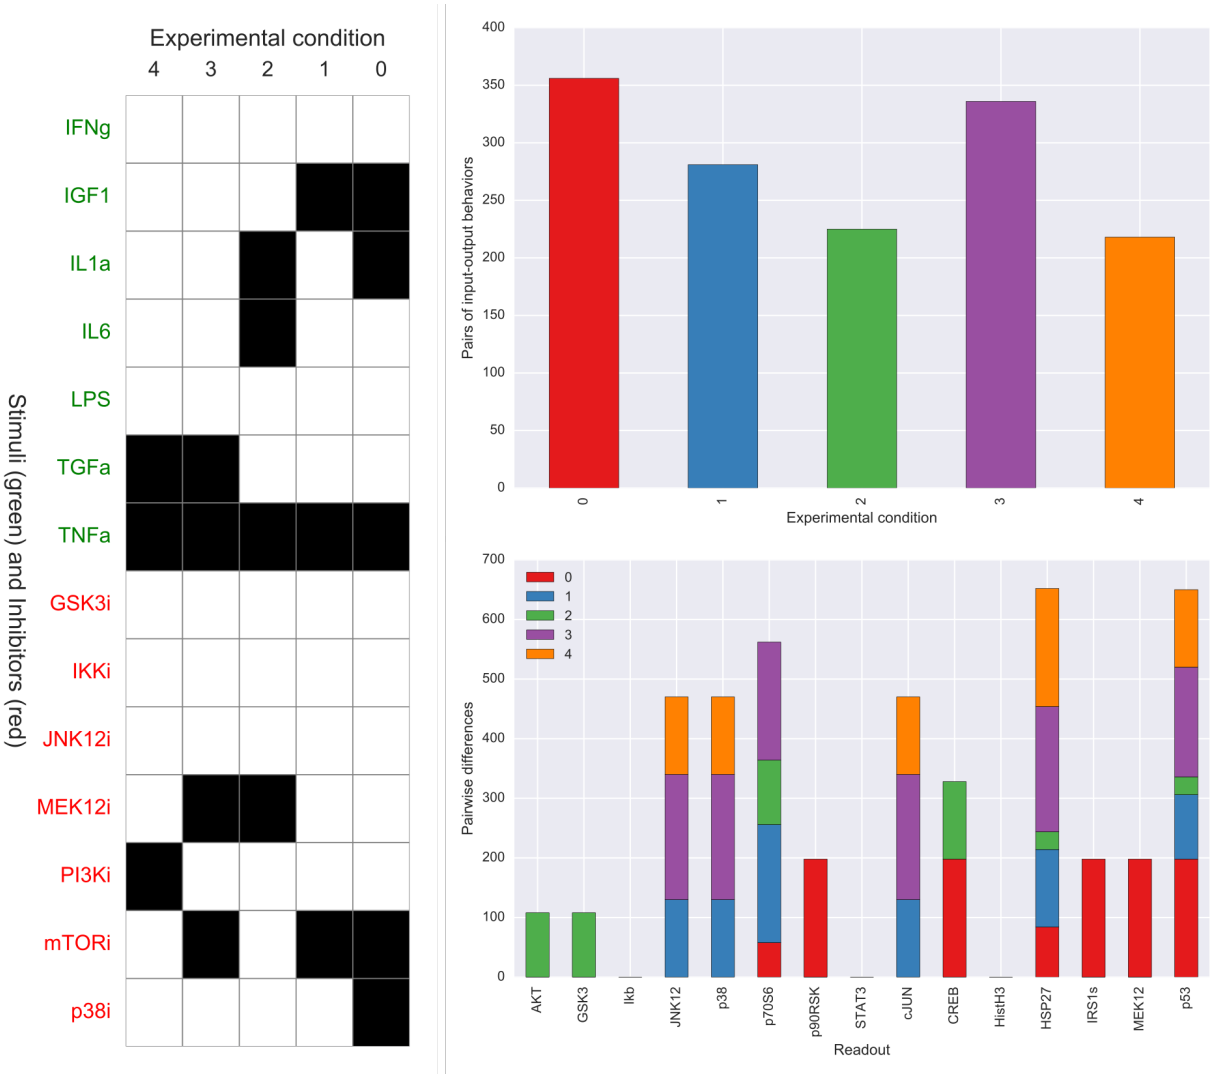
optional arguments:
  -h, --help      show this help message and exit
  --threads T     run clingo with given number of threads
  --conf C        threads configurations (Default to many)
  --stimuli S     maximum number of stimuli per experiment
  --inhibitors I  maximum number of inhibitors per experiment
  --nexp E        maximum number of experiments (Default to 10)
  --list L        list of possible experiments
  --relax         relax full pairwise discrimination (Default to False)
```

Run **caspo design**:

```
$ caspo design behaviors.csv setup.json

Running caspo design...
1 optimal experimental designs found in 219.5648s
```

The output of **caspo design** will be one csv file, namely, *designs.csv*, describing all optimal experimental designs. In addition, the following visualizations are provided for each experimental design in such a file. At the left we show all experimental conditions for each experimental design. At the top right we show the number of pairs of I/O behaviors discriminated by each experimental condition. At the bottom right we show the number of pairwise differences over specific readouts by each experimental condition.



2.2.4 Predict

This subcommands implements the prediction of all possible experimental condition using the ensemble of predictions from a given family of logical networks. Since predictions are based on a weighted average, a variance can also be computed to investigate the variability on every prediction. Again, the list of input-output behaviors generated by **caspo classify** can be used directly as the input for **caspo predict**. In fact, any list of logical networks could be used. However, it is recommended to use a list of representative logical networks (with their corresponding number of represented networks) for better performance.

Help on **caspo predict**:

```
$ caspo predict --help
usage: caspo predict [-h] networks setup

positional arguments:
  networks    logical networks in CSV format.
  setup       experimental setup in JSON format

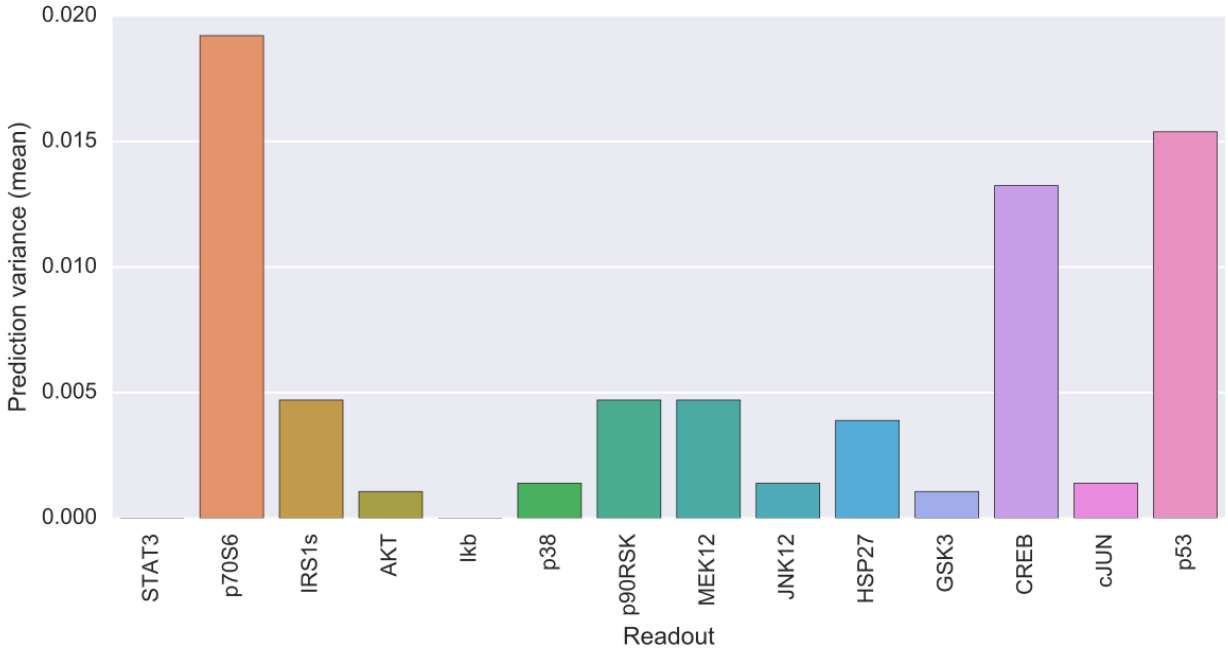
optional arguments:
  -h, --help  show this help message and exit
```

Run **caspo predict**:

```
$ caspo predict behaviors.csv setup.json

Running caspo predict...
Computing all predictions and their variance for 31 logical networks...
```

The output of **caspo predict** will be a csv file named *predictions.csv* describing for each possible experimental perturbation, the corresponding weighted average prediction and its variance for each readout. Also, the following visualization is provided showing the mean prediction variance for each readout over all possible experimental perturbations.



2.2.5 Control

This subcommand implements the control of a family of logical networks in terms of satisfying several intervention scenarios [4]. That is, it will find all intervention strategies for the given scenarios which are valid in every logical network in the family. Notably, the list of logical networks generated by **caspo learn** can be used directly as the input for **caspo control**. Further, other arguments allow for controlling the maximum number of interventions per strategy or whether interventions are allowed over constraints or goals.

Help on **caspo control**:

```
$ caspo control -h
usage: caspo control [-h] [--threads T] [--conf C] [--size M]
                     [--allow-constraints] [--allow-goals]
                     networks scenarios

positional arguments:
  networks              logical networks in CSV format
  scenarios             intervention scenarios in CSV format

optional arguments:
  -h, --help            show this help message and exit
  --threads T           run clingo with given number of threads
  --conf C              threads configurations (Default to many)
```

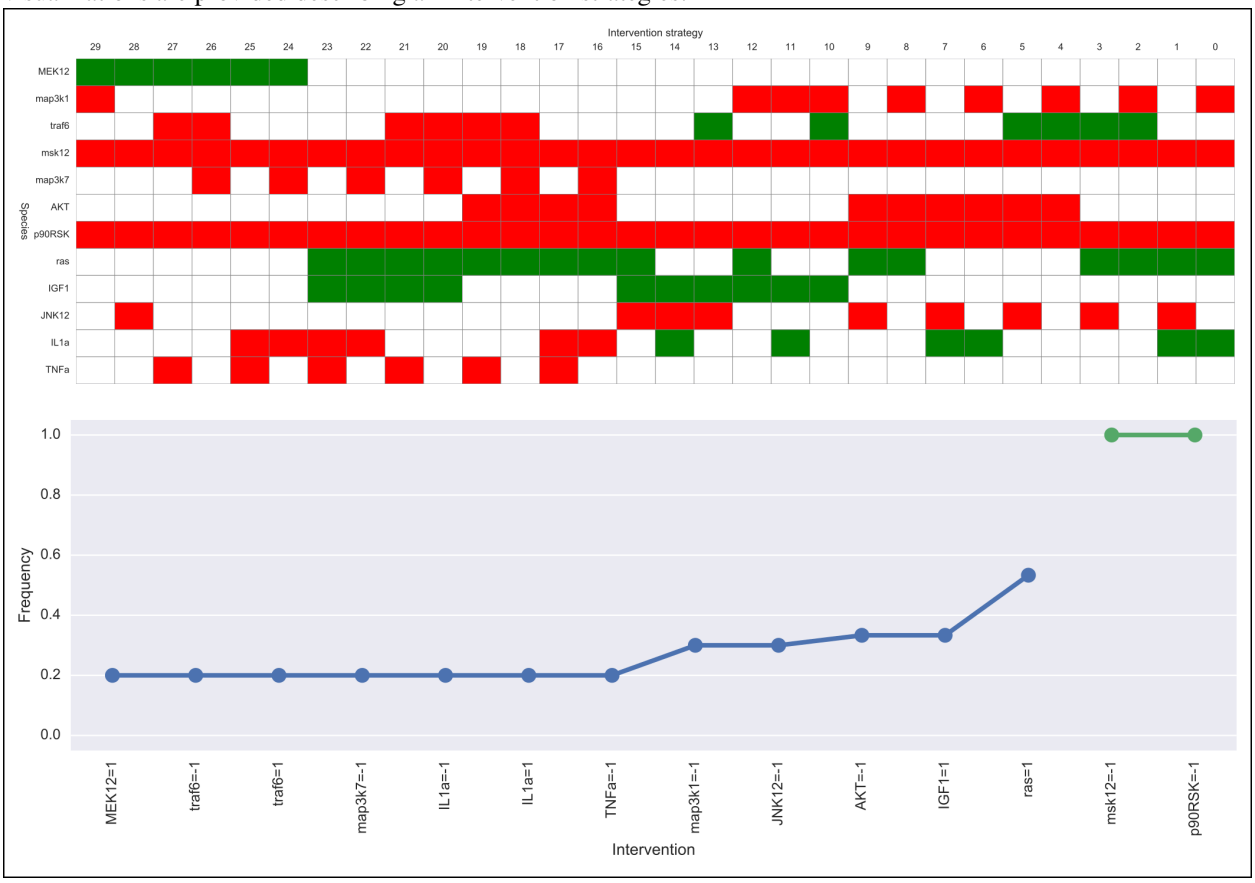
```
  --size M              maximum size for interventions strategies (Default to 0
                        (no limit))
  --allow-constraints   allow intervention over side constraints (Default to
                        False)
  --allow-goals         allow intervention over goals (Default to False)
```

Run **caspo control**:

```
$ caspo control networks.csv scenarios.csv

Running caspo control...
30 optimal intervention strategies found in 9.2413s
```

The output of **caspo control** will be two csv files, namely, *strategies.csv* and *stats-strategies.csv*. The file *strategies.csv* describes all intervention strategies found. The file *stats-strategies.csv* describes the frequency of each intervention over all strategies together with pairs of mutually inclusive/exclusive interventions. In addition, the following default visualizations are provided describing all intervention strategies:



2.2.6 Visualize

This subcommand implements all visualizations generated in other subcommands but to be run independently from the subcommand generating the data. This could be useful to visualize logical networks, experimental designs or intervention strategies not necessarily generated by **caspo**.

Help on **caspo visualize**:

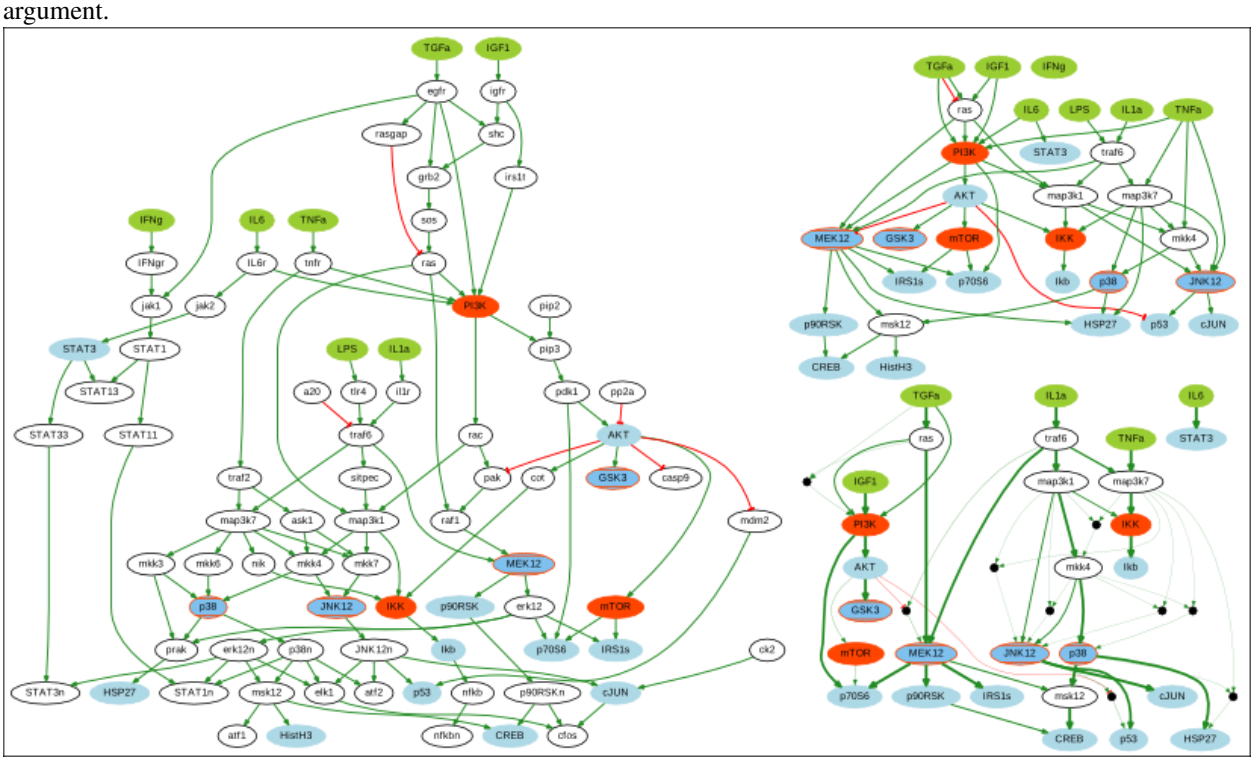
```
$ caspo visualize --help
usage: caspo visualize [-h] [--pkn P] [--setup S] [--networks N] [--midas M T]
                       [--sample R] [--stats-networks F] [--behaviors B]
                       [--designs D] [--predictions P] [--strategies S]
                       [--stats-strategies F]

optional arguments:
  -h, --help             show this help message and exit
  --pkn P                prior knowledge network in SIF format
  --setup S              experimental setup in JSON format
  --networks N           logical networks in CSV format
  --midas M T            experimental dataset in MIDAS file and time-point
  --sample R             visualize a sample of R logical networks or 0 for all
                         (Default to -1 (none))
  --stats-networks F     logical mappings frequencies in CSV format
  --behaviors B          logical networks in CSV format
  --designs D            experimental designs in CSV format
  --predictions P        logical predictions in CSV format
  --strategies S         intervention strategies in CSV format
  --stats-strategies F   intervention frequencies in CSV format
```

Run **caspo visualize**:

```
$ caspo visualize --pkn pkn.sif --networks networks.csv --setup setup.json
```

The output of **caspo visualize** will depend on the given arguments. Apart from the visualizations already shown when we described previous subcommands, it also provides visualization for a given PKN or a list of logical networks. Below we show an original PKN in the left, a compressed PKN in the top right, and the union of logical networks in the bottom right. Either all or a sample of logical networks can also be visualized individually using the `--sample` argument.



Note that PKNs and logical networks visualizations are generated as DOT files which can be either opened using a dot viewer or converted to different formats (pdf, ps, png, among others) using Graphviz. For example, you can convert

from dot to pdf by running:

```
$ dot pkn.dot -Tpdf -o pkn.pdf
```

2.2.7 Test

Help on **caspo test**:

```
$ caspo test --help
usage: caspo test [-h] [--threads T] [--conf C]
                  [--testcase {Toy,LiverToy,LiverDREAM,ExtLiver}]

optional arguments:
  -h, --help            show this help message and exit
  --threads T           run clingo with given number of threads
  --conf C              threads configurations (Default to many)
  --testcase {Toy,LiverToy,LiverDREAM,ExtLiver}
                        testcase name
```

Run **caspo test**:

```
$ caspo test

Testing caspo subcommands using test case Toy.

Copying files for running tests:
    Prior knowledge network: pkn.sif
    Phospho-proteomics dataset: dataset.csv
    Experimental setup: setup.json
    Intervention scenarios: scenarios.csv

$ caspo --out out learn out/pkn.sif out/dataset.csv 10 --fit 0.1 --size 5

Optimum logical network learned in 0.0066s
Optimum logical networks has MSE 0.1100 and size 7
5 (nearly) optimal logical networks learned in 0.0075s
Weighted MSE: 0.1100

$ caspo --out out classify out/networks.csv out/setup.json out/dataset.csv 10

Classifying 5 logical networks...
3 input-output logical behaviors found in 0.2029s
Weighted MSE: 0.1100

$ caspo --out out design out/behaviors.csv out/setup.json

1 optimal experimental designs found in 0.0047s

$ caspo --out out predict out/behaviors.csv out/setup.json

Computing all predictions and their variance for 3 logical networks...

$ caspo --out out control out/networks.csv out/scenarios.csv

3 optimal intervention strategies found in 0.0043s

$ caspo --out out visualize --pkn out/pkn.sif --setup out/setup.json \
        --networks out/networks.csv --midas out/dataset.csv 10 \
```

```
        --stats-networks=out/stats-networks.csv --behaviors out/behaviors.csv \
        --designs=out/designs.csv --predictions=out/predictions.csv \
        --strategies=out/strategies.csv --stats-strategies=out/stats-strategies.csv
```

CHAPTER 3

API Reference

3.1 Core

3.1.1 caspo.core.setup

class caspo.core.setup.**Setup**(*stimuli*, *inhibitors*, *readouts*)

Experimental setup describing stimuli, inhibitors and readouts species names

Parameters

- **stimuli** (*list[str]*) – List of stimuli species
- **inhibitors** (*list[str]*) – List of inhibitors species
- **readouts** (*list[str]*) – List of readouts species

stimuli

list[str]

inhibitors

list[str]

readouts

list[str]

__len__()

Returns the sum of stimuli, inhibitors, and readouts

Returns Sum of stimuli, inhibitors, and readouts

Return type int

clampings_iter(*cues=None*)

Iterates over all possible clampings of this experimental setup

Parameters **cues** (*Optional[iterable]*) – If given, restricts clampings over given species names

Yields *caspo.core.clamping.Clamping* – The next clamping with respect to the experimental setup

cues(*rename_inhibitors=False*)

Returns stimuli and inhibitors species of this experimental setup

Parameters **rename_inhibitors** (*boolean*) – If True, rename inhibitors with an ending 'i' as in MIDAS files.

Returns List of species names in order: first stimuli followed by inhibitors

Return type list

filter(*networks*)
Returns a new experimental setup restricted to species present in the given list of networks

Parameters **networks** (*caspo.core.logicalnetwork.LogicalNetworkList*) – List of logical networks

Returns The restricted experimental setup

Return type *caspo.core.setup.Setup*

classmethod from_json(*klass*, *filename*)
Creates an experimental setup from a JSON file

Parameters **filename** (*str*) – Absolute path to JSON file

Returns Created object instance

Return type *caspo.core.setup.Setup*

nodes
frozenset: unique species names in the experimental setup

to_funset()
Converts the experimental setup to a set of gringo.Fun object instances

Returns The set of gringo.Fun object instances

Return type set

to_json(*filename*)
Writes the experimental setup to a JSON file

Parameters **filename** (*str*) – Absolute path where to write the JSON file

3.1.2 caspo.core.literal

class caspo.core.literal.**Literal**
A literal is a variable or its negation

variable
str

signature
int (either 1 or -1)

__str__()
Returns the string representation of the literal

Returns String representation of the literal

Return type str

classmethod from_str(*klass*, *string*)
Creates a literal from a string

Parameters **string** (*str*) – If the string starts with '!', it's interpreted as a negated variable

Returns Created object instance

Return type *caspo.core.literal.Literal*

3.1.3 caspo.core.clamping

class caspo.core.clamping.**Clamping**

A clamping is a frozenset of *caspo.core.literal.Literal* object instances where each literal describes a clamped variable

bool(*variable*)

Returns whether the given variable is positively clamped

Parameters **variable** (*str*) – The variable name

Returns True if the given variable is positively clamped, False otherwise

Return type boolean

drop_literals(*literals*)

Returns a new clamping without the given literals

Parameters **literals** (iterable[*caspo.core.literal.Literal*]) – Iterable of literals to be removed

Returns A new clamping without the given literals

Return type *caspo.core.clamping.Clamping*

classmethod from_tuples(*klass*, *tuples*)

Creates a clamping from tuples of the form (variable, sign)

Parameters **tuples** (*iterable[(str,int)]*) – An iterable of tuples describing clamped variables

Returns Created object instance

Return type *caspo.core.clamping.Clamping*

has_variable(*variable*)

Returns whether the given variable is present in the clamping

Parameters **variable** (*str*) – The variable name

Returns True if the given variable is present in the clamping, False otherwise

Return type boolean

to_array(*variables*)

Converts the clamping to a 1-D array with respect to the given variables

Parameters **variables** (*list[str]*) – List of variables names

Returns 1-D array where position *i* correspond to the sign of the clamped variable at position *i* in the given list of variables

Return type numpy.ndarray

to_funset(*index*, *name='clamped'*)

Converts the clamping to a set of gringo.Fun object instances

Parameters

- **index** (*int*) – An external identifier to associate several clampings together in ASP
- **name** (*str*) – A function name for the clamping

Returns The set of gringo.Fun object instances

Return type set

class caspo.core.clamping.**ClampingList**

A list of *caspo.core.clamping.Clamping* object instances

combinatorics()

Returns mutually exclusive/inclusive clampings

Returns A tuple of 2 dictionaries. For each literal key, the first dict has as value the set of mutually exclusive clampings while the second dict has as value the set of mutually inclusive clampings.

Return type (dict,dict)

differences(*networks*, *readouts*, *prepend=''*)

Returns the total number of pairwise differences over the given readouts for the given networks

Parameters

- **networks** (iterable[*caspo.core.logicalnetwork.LogicalNetwork*]) – Iterable of logical networks to compute pairwise differences
- **readouts** (*list[str]*) – List of readouts species names
- **prepend** (*str*) – Columns are renamed using the given string at the beginning

Returns Total number of pairwise differences for each clamping over each readout

Return type pandas.DataFrame

drop_literals(*literals*)

Returns a new list of clampings without the given literals

Parameters **literals** (iterable[*caspo.core.literal.Literal*]) – Iterable of literals to be removed from each clamping

Returns The new list of clampings

Return type *caspo.core.clamping.ClampingList*

frequencies_iter()

Iterates over the frequencies of all clamped variables

Yields *tuple[caspo.core.literal.Literal, float]* – The next tuple of the form (literal, frequency)

frequency(*literal*)

Returns the frequency of a clamped variable

Parameters **literal** (*caspo.core.literal.Literal*) – The clamped variable

Returns The frequency of the given literal

Return type float

Raises ValueError – If the variable is not present in any of the clampings

classmethod from_csv(*klass*, *filename*, *inhibitors=[]*)

Creates a list of clampings from a CSV file. Column names are expected to be of the form *TR:species_name*

Parameters

- **filename** (*str*) – Absolute path to a CSV file to be loaded with pandas.read_csv. The resulting DataFrame is passed to *from_dataframe()*.
- **inhibitors** (*Optional[list[str]]*) – If given, species names ending with *i* and found in the list (without the *i*) will be interpreted as inhibitors. That is, if they are set to

1, the corresponding species is inhibited and therefore its negatively clamped. Apart from that, all 1s (resp. 0s) are interpreted as positively (resp. negatively) clamped.

Otherwise (if inhibitors=[]), all 1s (resp. -1s) are interpreted as positively (resp. negatively) clamped.

Returns Created object instance

Return type *caspo.core.clamping.ClampingList*

classmethod **from_dataframe**(*klass*, *df*, *inhibitors=[]*)

Creates a list of clampings from a pandas.DataFrame object instance. Column names are expected to be of the form *TR:species_name*

Parameters

- **df** (pandas.DataFrame) – Columns and rows correspond to species names and individual clampings, respectively.
- **inhibitors** (*Optional[list[str]]*) – If given, species names ending with *i* and found in the list (without the *i*) will be interpreted as inhibitors. That is, if they are set to 1, the corresponding species is inhibited and therefore its negatively clamped. Apart from that, all 1s (resp. 0s) are interpreted as positively (resp. negatively) clamped.

  Otherwise (if inhibitors=[]), all 1s (resp. -1s) are interpreted as positively (resp. negatively) clamped.

Returns Created object instance

Return type caspo.core.ClampingList

to_csv(*filename*, *stimuli=[]*, *inhibitors=[]*, *prepend=''*)

Writes the list of clampings to a CSV file

Parameters

- **filename** (*str*) – Absolute path where to write the CSV file
- **stimuli** (*Optional[list[str]]*) – List of stimuli names. If given, stimuli are converted to {0,1} instead of {-1,1}.
- **inhibitors** (*Optional[list[str]]*) – List of inhibitors names. If given, inhibitors are renamed and converted to {0,1} instead of {-1,1}.
- **prepend** (*str*) – Columns are renamed using the given string at the beginning

to_dataframe(*stimuli=[]*, *inhibitors=[]*, *prepend=''*)

Converts the list of clampigns to a pandas.DataFrame object instance

Parameters

- **stimuli** (*Optional[list[str]]*) – List of stimuli names. If given, stimuli are converted to {0,1} instead of {-1,1}.
- **inhibitors** (*Optional[list[str]]*) – List of inhibitors names. If given, inhibitors are renamed and converted to {0,1} instead of {-1,1}.
- **prepend** (*str*) – Columns are renamed using the given string at the beginning

Returns DataFrame representation of the list of clampings

Return type pandas.DataFrame

to_funset(*lname='clamping'*, *cname='clamped'*)

Converts the list of clampings to a set of gringo.Fun instances

Parameters

- **lname** (*str*) – Predicate name for the clamping id
- **cname** (*str*) – Predicate name for the clamped variable

Returns Representation of all clampings as a set of gringo.Fun instances

Return type set

3.1.4 caspo.core.dataset

class caspo.core.dataset.**Dataset**(*midas*, *time*)

An experimental phospho-proteomics dataset extending pandas.DataFrame

Parameters

- **midas** (*Absolute PATH to a MIDAS file*) –
- **time** (*Data acquisition time-point for the early response*) –

setup

caspo.core.setup.Setup

clampings

caspo.core.clamping.ClampingList

readouts

pandas.DataFrame

is_inhibitor(*name*)

Returns if the given species name is a inhibitor or not

Parameters **name** (*str*) –

Returns True if the given name is a inhibitor, False otherwise.

Return type boolean

is_readout(*name*)

Returns if the given species name is a readout or not

Parameters **name** (*str*) –

Returns True if the given name is a readout, False otherwise.

Return type boolean

is_stimulus(*name*)

Returns if the given species name is a stimulus or not

Parameters **name** (*str*) –

Returns True if the given name is a stimulus, False otherwise.

Return type boolean

to_funset(*discrete*)

Converts the dataset to a set of gringo.Fun instances

Parameters **discrete** (*callable*) – A discretization function

Returns Representation of the dataset as a set of gringo.Fun instances

Return type set

3.1.5 caspo.core.graph

class caspo.core.graph.**Graph**
Prior knowledge network (aka interaction graph) extending networkx.MultiDiGraph

__plot__()
Returns a copy of this graph ready for plotting

Returns A copy of the object instance

Return type *caspo.core.graph.Graph*

compress(*setup*)
Returns the compressed graph according to the given experimental setup

Parameters **setup** (*caspo.core.setup.Setup*) – Experimental setup used to compress the graph

Returns Compressed graph

Return type *caspo.core.graph.Graph*

classmethod from_tuples(*klass*, *tuples*)
Creates a graph from an iterable of tuples describing edges like (source, target, sign)

Parameters **tuples** (*iterable[(str,str,int)]*) – Tuples describing signed and directed edges

Returns Created object instance

Return type *caspo.core.graph.Graph*

predecessors(*node*, *exclude_compressed=True*)
Returns the list of predecessors of a given node

Parameters

- **node** (*str*) – The target node
- **exclude_compressed** (*boolean*) – If true, compressed nodes are excluded from the predecessors list

Returns List of predecessors nodes

Return type list

classmethod read_sif(*klass*, *path*)
Creates a graph from a simple interaction format (SIF) file

Parameters **path** (*str*) – Absolute path to a SIF file

Returns Created object instance

Return type *caspo.core.graph.Graph*

successors(*node*, *exclude_compressed=True*)
Returns the list of successors of a given node

Parameters

- **node** (*str*) – The target node
- **exclude_compressed** (*boolean*) – If true, compressed nodes are excluded from the successors list

Returns List of successors nodes

Return type list

3.1.6 caspo.core.hypergraph

class caspo.core.hypergraph.**HyperGraph**(*nodes*, *hyper*, *edges*)

Signed and directed hypergraph representation providing the link between logical networks and the corresponding expanded prior knowledge network.

Parameters

- **nodes** (pandas.Series) – Values in the Series correspond to variables names
- **hyper** (pandas.Series) – Values in the Series correspond to the index in attribute *nodes* (interpreted as the target node)
- **edges** (pandas.DataFrame) – Hyperedges details as a DataFrame with columns *hyper_idx* (corresponds to the index in attribute *hyper*), *name* (interpreted as a source node), and *sign* (1 or -1)

nodes
pandas.Series

hyper
pandas.Series

edges
pandas.DataFrame

clauses
dict

A mapping from an hyperedge id (*hyper_idx*) to a *caspo.core.clause.Clause* object instance

clauses_idx
dict

The inverse mappings of those in attribute *clauses*

mappings
caspo.core.mapping.MappingList

The list of all possible *caspo.core.mapping.Mapping* for this hypergraph

classmethod from_graph(*klass*, *graph*, *length=0*)

Creates a hypergraph (expanded graph) from a *caspo.core.graph.Graph* object instance

Parameters

- **graph** (*caspo.core.graph.Graph*) – The base interaction graph to be expanded
- **length** (*int*) – Maximum length for hyperedges source sets. If 0, use maximum possible in each case.

Returns Created object instance

Return type *caspo.core.hypergraph.HyperGraph*

to_funset()

Converts the hypergraph to a set of gringo.Fun instances

Returns Representation of the hypergraph as a set of gringo.Fun instances

Return type set

variable(*index*)
Returns the variable name for a given variable id

Parameters **index** (*int*) – Variable id

Returns Variable name

Return type str

3.1.7 caspo.core.mapping

class caspo.core.mapping.**Mapping**
A logical conjunction mapping as a tuple made of a *caspo.core.clause.Clause* and a target

clause
caspo.core.clause.Clause

target
str

__str__()
Returns the string representation of the mapping

Returns String representation of the mapping as *target*<=*clause*

Return type str

classmethod from_str(*klass*, *string*)
Creates a mapping from a string

Parameters **string** (*str*) – String of the form *target*<-*clause* where *clause* is a valid string for *caspo.core.clause.Clause*

Returns Created object instance

Return type *caspo.core.mapping.Mapping*

class caspo.core.mapping.**MappingList**(*mappings*, *indexes=None*)
A list of indexed *caspo.core.mapping.Mapping* objects.

Parameters

- **mappings** ([*caspo.core.mapping.Mapping*]) – The list of logical mappings
- **indexes** (*[int]*) – An optional list of integers to use as indexes

__getitem__(*index*)
A list of mappings can be indexed by:

1. a tuple *caspo.core.mapping.Mapping* to get its corresponding index
2. a list of integers to get all the corresponding mappings objects
3. a single integer to get its corresponding mapping object

Returns An integer, a MappingList or a single mapping

Return type object

__iter__()
Iterates over mappings

Yields *caspo.core.mapping.Mapping* – The next logical mapping

__len__()
Returns the number of mappings

Returns Number of mappings

Return type int

iteritems()
Iterates over all mappings

Yields *(int,Mapping)* – The next pair (index, mapping)

3.1.8 caspo.core.clause

class caspo.core.clause.**Clause**
A conjunction clause is a frozenset of *caspo.core.literal.Literal* object instances

__str__()
Returns the string representation of the clause

bool(*state*)
Returns the Boolean evaluation of the clause with respect to a given state

Parameters **state** (*dict*) – Key-value mapping describing a Boolean state or assignment

Returns The evaluation of the clause with respect to the given state or assignment

Return type boolean

classmethod from_str(*klass*, *string*)
Creates a clause from a given string.

Parameters **string** (*str*) – A string of the form *a+!b* which translates to *a AND NOT b*.

Returns Created object instance

Return type *caspo.core.clause.Clause*

3.1.9 caspo.core.logicalnetwork

class caspo.core.logicalnetwork.**LogicalNetwork**
Logical network class extends networkx.DiGraph with nodes being, either *caspo.core.clause.Clause* object instances or species names (str).

networks
int

Number of networks having the same behavior (including this network as the representative network)

__plot__()
Returns a networkx.MultiDiGraph ready for plotting.

Returns Network object instance ready for plotting

Return type networkx.MultiDiGraph

fixpoint(*clamping*, *steps=0*)
Computes the fixpoint with respect to a given *caspo.core.clamping.Clamping*

Parameters

- **clamping** (*caspo.core.clamping.Clamping*) – The clamping with respect to the fixpoint is computed

- **steps** (*int*) – If greater than zero, a maximum number of steps is performed. Otherwise it continues until reaching a fixpoint. Note that if no fixpoint exists, e.g. a network with a negative feedback-loop, this will never end unless you provide a maximum number of steps.

Returns The key-value mapping describing the state of the logical network

Return type dict

formulas_iter()
Iterates over all variable-clauses in the logical network

Yields *tuple[str,frozenset[caspo.core.clause.Clause]]* – The next tuple of the form (variable, set of clauses) in the logical network.

classmethod from_hypertuples(*klass*, *hg*, *tuples*)
Creates a logical network from an iterable of integer tuples matching mappings in the given *caspo.core.hypergraph.HyperGraph*

Parameters

- **hg** (*caspo.core.hypergraph.HyperGraph*) – Underlying hypergraph
- **tuples** (*(int,int)*) – tuples matching mappings in the given hypergraph

Returns Created object instance

Return type *caspo.core.logicalnetwork.LogicalNetwork*

predictions(*clampings*, *readouts*, *stimuli=[]*, *inhibitors=[]*, *nclampings=-1*)
Computes network predictions for the given iterable of clampings

Parameters

- **clampings** (*iterable*) – Iterable over clampings
- **readouts** (*list[str]*) – List of readouts names
- **stimuli** (*Optional[list[str]]*) – List of stimuli names
- **inhibitors** (*Optional[list[str]]*) – List of inhibitors names
- **nclampings** (*Optional[int]*) – If greater than zero, it must be the number of clampings in the iterable. Otherwise, clampings must implement the special method `__len__()`

Returns DataFrame with network predictions for each clamping. If stimuli and inhibitors are given, columns are included describing each clamping. Otherwise, columns correspond to readouts only.

Return type pandas.DataFrame

size
int: The size (complexity) of this logical network as the sum of clauses' length

step(*state*, *clamping*)
Performs a simulation step from the given state and with respect to the given clamping

Parameters

- **state** (*dict*) – The key-value mapping describing the current state of the logical network
- **clamping** (*caspo.core.clamping.Clamping*) – A clamping over variables in the logical network

Returns The key-value mapping describing the next state of the logical network

Return type dict

to_array(*mappings*)
Converts the logical network to a binary array with respect to the given mappings from a *caspo.core.hypergraph.HyperGraph* object instance.

Parameters **mappings** (*caspo.core.mapping.MappingList*) – Mappings to create the binary array

Returns Binary array with respect to the given mappings describing the logical network. Position *i* in the array will be 1 if the network has the mapping at position *i* in the given list of mappings.

Return type numpy.ndarray

to_graph()
Converts the logical network to its underlying interaction graph

Returns The underlying interaction graph

Return type *caspo.core.graph.Graph*

variables()
Returns variables in the logical network

Returns Unique variables names

Return type set[str]

class caspo.core.logicalnetwork.**LogicalNetworkList**(*hg*, *matrix=None*, *networks=None*)
List of *caspo.core.logicalnetwork.LogicalNetwork* object instances

Parameters

- **hg** (*caspo.core.hypergraph.HyperGraph*) – Underlying hypergraph of all logical networks.
- **matrix** (Optional[numpy.ndarray]) – 2-D binary array representation of all logical networks. If None, an empty array is initialised
- **networks** (Optional[numpy.ndarray]) – For each network in the list, it gives the number of networks having the same behavior. If None, an array of ones is initialised with the same length as the number of networks in the list.

__getitem__(*index*)
Returns logical network(s) at the given index

Parameters **index** (*object*) – It can be an int or an iterable of int

Returns Either a *caspo.core.logicalnetwork.LogicalNetwork* or a *caspo.core.logicalnetwork.LogicalNetworkList* object

Return type object

__iter__()
Iterates over all logical networks in the list

Yields *caspo.core.logicalnetwork.LogicalNetwork* – The next logical network in the list

__len__()
Returns the number of logical networks

Returns Number of logical networks

Return type int

__plot__()
Returns a networkx.MultiDiGraph ready for plotting. Edges weights correspond to mappings frequencies.

Returns Network object instance ready for plotting

Return type networkx.MultiDiGraph

add_network(*pos*, *network*)
Adds a network to the logical network at the given position

append(*network*)
Append a *caspo.core.logicalnetwork.LogicalNetwork* to the list

Parameters **network** (*caspo.core.logicalnetwork.LogicalNetwork*) – The network to append

combinatorics()
Returns mutually exclusive/inclusive mappings

Returns A tuple of 2 dictionaries. For each mapping key, the first dict has as value the set of mutually exclusive mappings while the second dict has as value the set of mutually inclusive mappings.

Return type (dict,dict)

concat(*other*)
Returns the concatenation with another *caspo.core.logicalnetwork.LogicalNetworkList* object instance. It is assumed (not checked) that both have the same underlying hypergraph.

Parameters **other** (*caspo.core.logicalnetwork.LogicalNetworkList*) – The list to concatenate

Returns If other is empty returns self, if self is empty returns other, otherwise a new `caspo.core.LogicalNetworkList` is created by concatenating self and other.

Return type *caspo.core.logicalnetwork.LogicalNetworkList*

frequencies_iter()
Iterates over all non-zero frequencies of logical conjunction mappings in this list

Yields *tuple[caspo.core.mapping.Mapping, float]* – The next pair (mapping,frequency)

frequency(*mapping*)
Returns frequency of a given *caspo.core.mapping.Mapping*

Parameters **mapping** (*caspo.core.mapping.Mapping*) – A logical conjuntion mapping

Returns Frequency of the given mapping over all logical networks

Return type float

Raises `ValueError` – If the given mapping is not found in the mappings of the underlying hypergraph of this list

classmethod **from_csv**(*klass*, *filename*)
Creates a list of logical networks from a CSV file. Columns that cannot be parsed as a *caspo.core.mapping.Mapping* are ignored except for a column named *networks* which (if present) is interpreted as the number of logical networks having the same input-output behavior.

Parameters **filename** (*str*) – Absolute path to CSV file

Returns Created object instance

Return type *caspo.core.logicalnetwork.LogicalNetworkList*

classmethod from_hypergraph(*klass*, *hypergraph*, *networks=[]*)
Creates a list of logical networks from a given hypergraph and an optional list of *caspo.core.logicalnetwork.LogicalNetwork* object instances

Parameters

- **hypegraph** (*caspo.core.hypergraph.HyperGraph*) – Underlying hypergraph for this logical network list
- **networks** (*Optional[list]*) – List of *caspo.core.logicalnetwork.LogicalNetwork* object instances

Returns Created object instance

Return type *caspo.core.logicalnetwork.LogicalNetworkList*

mappings
caspo.core.mapping.MappingList: the list of mappings present in at least one logical network in this list

predictions(*setup*, *n_jobs=-1*)
Returns a pandas.DataFrame with the weighted average predictions and variance of all readouts for each possible clampings in the given experimental setup. For each logical network the weight corresponds to the number of networks having the same behavior.

Parameters

- **setup** (*caspo.core.setup.Setup*) – Experimental setup
- **n_jobs** (*int*) – Number of jobs to run in parallel. Default to -1 (all cores available)

Returns DataFrame with the weighted average predictions and variance of all readouts for each possible clamping

Return type pandas.DataFrame

See also:

Wikipedia: Weighted sample variance

reset()
Drop all networks in the list

split(*indices*)
Splits logical networks according to given indices

Parameters **indices** (*list*) – 1-D array of sorted integers, the entries indicate where the array is split

Returns List of *caspo.core.logicalnetwork.LogicalNetworkList* object instances

Return type list

See also:

numpy.split

to_csv(*filename*, *networks=False*, *dataset=None*, *size=False*, *n_jobs=-1*)
Writes the list of logical networks to a CSV file

Parameters

- **filename** (*str*) – Absolute path where to write the CSV file

- **networks** (*boolean*) – If True, a column with number of networks having the same behavior is included in the file
- **dataset** (Optional[*caspo.core.dataset.Dataset*]) – If not None, a column with the MSE with respect to the given dataset is included
- **size** (*boolean*) – If True, a column with the size of each logical network is included
- **n_jobs** (*int*) – Number of jobs to run in parallel. Default to -1 (all cores available)

to_dataframe(*networks=False*, *dataset=None*, *size=False*, *n_jobs=-1*)
Converts the list of logical networks to a pandas.DataFrame object instance

Parameters

- **networks** (*boolean*) – If True, a column with number of networks having the same behavior is included in the DataFrame
- **dataset** (Optional[*caspo.core.dataset.Dataset*]) – If not None, a column with the MSE with respect to the given dataset is included in the DataFrame
- **size** (*boolean*) – If True, a column with the size of each logical network is included in the DataFrame
- **n_jobs** (*int*) – Number of jobs to run in parallel. Default to -1 (all cores available)

Returns DataFrame representation of the list of logical networks.

Return type pandas.DataFrame

to_funset()
Converts the list of logical networks to a set of gringo.Fun instances

Returns Representation of all networks as a set of gringo.Fun instances

Return type set

weighted_mse(*dataset*, *n_jobs=-1*)
Returns the weighted MSE over all logical networks with respect to the given *caspo.core.dataset.Dataset* object instance. For each logical network the weight corresponds to the number of networks having the same behavior.

Parameters

- **dataset** (*caspo.core.dataset.Dataset*) – Dataset to compute MSE
- **n_jobs** (*int*) – Number of jobs to run in parallel. Default to -1 (all cores available)

Returns Weighted MSE

Return type float

3.2 Modules

3.2.1 Learn

class caspo.learn.**Learner**(*graph*, *dataset*, *length*, *discrete*, *factor*)
Learner of (nearly) optimal logical networks with respect to a given prior knownledge network and a phosphoproteomics dataset.

Parameters

- **graph** (*caspo.core.graph.Graph*) – Prior knowledge network

- **dataset** (*caspo.core.dataset.Dataset*) – Experimental dataset
- **length** (*int*) – Maximum length for conjunction clauses
- **discrete** (*str*) – Discretization function: *round*, *ceil*, or *floor*
- **factor** (*int*) – Discretization factor, e.g. 10, 100, 1000

graph
caspo.core.graph.Graph

dataset
caspo.core.dataset.Dataset

length
int

factor
int

discrete
str

hypergraph
caspo.core.hypergraph.HyperGraph

instance
str

optimum
caspo.core.logicalnetwork.LogicalNetwork

networks
caspo.core.logicalnetwork.LogicalNetworkList

encodings
dict

stats
dict

ceil(*factor*, *value*)
Discretize a given value using a given factor and the ceil integer function

Parameters

- **factor** (*int*) – The factor to be used for the discretization
- **value** (*float*) – The value to be discretized

Returns The discretized value

Return type int

floor(*factor*, *value*)
Discretize a given value using a given factor and the floor integer function

Parameters

- **factor** (*int*) – The factor to be used for the discretization
- **value** (*float*) – The value to be discretized

Returns The discretized value

Return type int

learn (*fit=0*, *size=0*, *configure=None*)
Learns all (nearly) optimal logical networks with give fitness and size tolerance. The first optimum logical network found is saved in the attribute *optimum* while all enumerated logical networks are saved in the attribute *networks*.

Example:

```
>>> from caspo import core, learn

>>> graph = core.Graph.read_sif('pkn.sif')
>>> dataset = core.Dataset('dataset.csv', 30)
>>> zipped = graph.compress(dataset.setup)

>>> learner = learn.Learner(zipped, dataset, 2, 'round', 100)
>>> learner.learn(0.02, 1)

>>> learner.networks.to_csv('networks.csv')
```

Parameters

- **fit** (*float*) – Fitness tolerance, e.g., use 0.1 for 10% tolerance with respect to the optimum
- **size** (*int*) – Size tolerance with respect to the optimum
- **configure** (*callable*) – Callable object responsible of setting a custom clingo configuration

random (*size*, *n_and*, *max_in*, *n=1*)
Generates *n* random logical networks with given size range, number of AND gates and maximum input signals for AND gates. Logical networks are saved in the attribute *networks*.

Parameters

- **n** (*int*) – Number of random logical networks to be generated
- **size** (*(int,int)*) – Minimum and maximum sizes
- **n_and** (*(int,int)*) – Minimum and maximum AND gates
- **max_in** (*int*) – Maximum input signals for AND gates

round (*factor*, *value*)
Discretize a given value using a given factor and the closest integer function

Parameters

- **factor** (*int*) – The factor to be used for the discretization
- **value** (*float*) – The value to be discretized

Returns The discretized value

Return type int

3.2.2 Classify

class caspo.classify.**Classifier** (*networks*, *setup*)
Classifier of given list of logical networks with respect to a given experimental setup.

Parameters

- **networks** (*caspo.core.logicalnetwork.LogicalNetworkList*) – The list of logical networks
- **setup** (*caspo.core.setup.Setup*) – The experimental setup with respect to which the input-output behaviors must be computed

networks
caspo.core.logicalnetwork.LogicalNetworkList

setup
caspo.core.setup.Setup

stats
dict

classify(*n_jobs=-1*, *configure=None*)
Returns input-output behaviors for the list of logical networks in the attribute *networks*

Example:

```
>>> from caspo import core, classify

>>> networks = core.LogicalNetworkList.from_csv('networks.csv')
>>> setup = core.Setup.from_json('setup.json')

>>> classifier = classify.Classifier(networks, setup)
>>> behaviors = classifier.classify()

>>> behaviors.to_csv('behaviors.csv', networks=True)
```

n_jobs [int] Number of jobs to run in parallel. Default to -1 (all cores available)

configure [callable] Callable object responsible of setting clingo configuration

Returns The list of networks with one representative for each behavior

Return type *caspo.core.logicalnetwork.LogicalNetworkList*

3.2.3 Design

class caspo.design.**Designer**(*networks*, *setup*, *candidates=None*)
Experimental designer to discriminate among a list of logical networks (input-output behaviors representatives)

Parameters

- **networks** (*caspo.core.logicalnetwork.LogicalNetworkList*) – List of logical networks to discriminate
- **setup** (*caspo.core.setup.Setup*) – Experimental setup
- **candidates** (*caspo.core.clamping.ClampingList*) – Optional list of candidate experiments given as a list of clampings

networks
caspo.core.logicalnetwork.LogicalNetworkList

setup
caspo.core.setup.Setup

candidates
caspo.core.clamping.ClampingList

designs
list[*caspo.core.clamping.ClampingList*]

instance
str

encodings
dict

stats
dict

design(*max_stimuli=-1*, *max_inhibitors=-1*, *max_experiments=10*, *relax=False*, *configure=None*)
Finds all optimal experimental designs using up to `max_experiments` experiments, such that each experiment has up to `max_stimuli` stimuli and `max_inhibitors` inhibitors. Each optimal experimental design is appended in the attribute *designs* as an instance of *caspo.core.clamping.ClampingList*.

Example:

```
>>> from caspo import core, design
>>> networks = core.LogicalNetworkList.from_csv('behaviors.csv')
>>> setup = core.Setup.from_json('setup.json')

>>> designer = design.Designer(networks, setup)
>>> designer.design(3, 2)

>>> for i,d in enumerate(designer.designs):
...     f = 'design-%s' % i
...     d.to_csv(f, stimuli=self.setup.stimuli, inhibitors=self.setup.inhibitors)
```

Parameters

- **max_stimuli** (*int*) – Maximum number of stimuli per experiment
- **max_inhibitors** (*int*) – Maximum number of inhibitors per experiment
- **max_experiments** (*int*) – Maximum number of experiments per design
- **relax** (*boolean*) – Whether to relax the full-pairwise networks discrimination (True) or not (False). If relax equals True, the number of experiments per design is fixed to `max_experiments`
- **configure** (*callable*) – Callable object responsible of setting clingo configuration

3.2.4 Predict

class `caspo.predict.`**Predictor**(*networks*, *setup*)
Predictor of all possible experimental conditions over a given experimental setup using a given list of logical networks.

Parameters

- **networks** (*caspo.core.logicalnetwork.LogicalNetworkList*) – The list of logical networks used to generate the ensemble of predictions
- **setup** (*caspo.core.setup.Setup*) – The experimental setup to generate possible experimental conditions

networks
caspo.core.logicalnetwork.LogicalNetworkList

setup
caspo.core.setup.Setup

predict()
Computes all possible weighted average predictions and their variances

Example:

```
>>> from caspo import core, predict

>>> networks = core.LogicalNetworkList.from_csv('behaviors.csv')
>>> setup = core.Setup.from_json('setup.json')

>>> predictor = predict.Predictor(networks, setup)
>>> df = predictor.predict()

>>> df.to_csv('predictions.csv'), index=False)
```

Returns DataFrame with the weighted average predictions and variance of all readouts for each possible clamping

Return type pandas.DataFrame

3.2.5 Control

class caspo.control.**Controller**(*networks*, *scenarios*)
Controller of logical networks family for various intervention scenarios

Parameters

- **networks** (*caspo.core.logicalnetwork.LogicalNetworkList*) – List of logical networks
- **scenarios** (*caspo.control.ScenarioList*) – List of intervention scenarios

networks
caspo.core.logicalnetwork.LogicalNetworkList

scenarios
caspo.control.ScenarioList

strategies
caspo.core.clamping.ClampingList

instance
str

encodings
dict

stats
dict

control(*size=0*, *configure=None*)
Finds all inclusion-minimal intervention strategies up to the given size. Intervention strategies found are saved in the attribute *strategies* as a *caspo.core.clamping.ClampingList* object instance.

Example:

```
>>> from caspo import core, control

>>> networks = core.LogicalNetworkList.from_csv('networks.csv')
>>> scenarios = control.ScenarioList('scenarios.csv')

>>> controller = control.Controller(networks, scenarios)
>>> controller.control()

>>> controller.strategies.to_csv('strategies.csv')
```

Parameters

- **size** (*int*) – Maximum number of intervention per intervention strategy
- **configure** (*callable*) – Callable object responsible of setting clingo configuration

class caspo.control.**ScenarioList**(*filename*, *allow_constraints=False*, *allow_goals=False*)

List of intervention scenarios

Parameters

- **filename** (*str*) – Absolute PATH to a CSV file specifying several intervention scenarios
- **allow_constraints** (*boolean*) – Either to allow intervention over constraints or not
- **allow_goals** (*boolean*) – Either to allow intervention over goals or not

constraints

caspo.core.clamping.ClampingList

goals

caspo.core.clamping.ClampingList

to_funset()

Converts the intervention scenarios to a set of gringo.Fun instances

Returns Representation of the intervention scenarios as a set of gringo.Fun instances

Return type set

3.2.6 Visualize

caspo.visualize.**behaviors_distribution**(*df*, *filepath=None*)

Plots the distribution of logical networks across input-output behaviors. Optionally, input-output behaviors can be grouped by MSE.

Parameters

- **df** (pandas.DataFrame) – DataFrame with columns *networks* and optionally *mse*
- **filepath** (*str*) – Absolute path to a folder where to write the plot

Returns Generated plot

Return type plot

caspo.visualize.**coloured_network**(*network*, *setup*, *filename*)

Plots a coloured (hyper-)graph to a dot file

Parameters

- **network** (*object*) – An object implementing a method *__plot__* which must return the networkx.MultiDiGraph instance to be coloured. Typically, it will be an instance of either *caspo.core.graph.Graph*, *caspo.core.logicalnetwork.LogicalNetwork* or *caspo.core.logicalnetwork.LogicalNetworkList*
- **setup** (*caspo.core.setup.Setup*) – Experimental setup to be coloured in the network

caspo.visualize.**differences_distribution**(*df*, *filepath=None*)
For each experimental design it plot all the corresponding generated differences in different plots

Parameters

- **df** (pandas.DataFrame) – DataFrame with columns *id*, *pairs*, and starting with *DIF:*
- **filepath** (*str*) – Absolute path to a folder where to write the plots

Returns Generated plots

Return type list

caspo.visualize.**experimental_designs**(*df*, *filepath=None*)
For each experimental design it plot all the corresponding experimental conditions in a different plot

Parameters

- **df** (pandas.DataFrame) – DataFrame with columns *id* and starting with *TR:*
- **filepath** (*str*) – Absolute path to a folder where to write the plot

Returns Generated plots

Return type list

caspo.visualize.**intervention_strategies**(*df*, *filepath=None*)
Plots all intervention strategies

Parameters

- **df** (pandas.DataFrame) – DataFrame with columns starting with *TR:*
- **filepath** (*str*) – Absolute path to a folder where to write the plot

Returns Generated plot

Return type plot

caspo.visualize.**interventions_frequency**(*df*, *filepath=None*)
Plots the frequency of occurrence for each intervention

Parameters

- **df** (pandas.DataFrame) – DataFrame with columns *frequency* and *intervention*
- **filepath** (*str*) – Absolute path to a folder where to write the plot

Returns Generated plot

Return type plot

caspo.visualize.**mappings_frequency**(*df*, *filepath=None*)
Plots the frequency of logical conjunction mappings

Parameters

- **df** (pandas.DataFrame) – DataFrame with columns *frequency* and *mapping*

- **filepath** (*str*) – Absolute path to a folder where to write the plot

Returns Generated plot

Return type plot

caspo.visualize.**networks_distribution**(*df*, *filepath=None*)

Generates two alternative plots describing the distribution of variables *mse* and *size*. It is intended to be used over a list of logical networks.

Parameters

- **df** (pandas.DataFrame) – DataFrame with columns *mse* and *size*
- **filepath** (*str*) – Absolute path to a folder where to write the plots

Returns Generated plots

Return type tuple

caspo.visualize.**predictions_variance**(*df*, *filepath=None*)

Plots the mean variance prediction for each readout

Parameters

- **df** (pandas.DataFrame) – DataFrame with columns starting with *VAR:*
- **filepath** (*str*) – Absolute path to a folder where to write the plots

Returns Generated plot

Return type plot
